Artificial intelligence (AI) is intelligence demonstrated by machines, in contrast to the natural intelligence displayed by humans and animals. Leading AI textbooks define the field as the study of "intelligent agents": any device that perceives its environment and takes actions that maximize its chance of successfully achieving its goals. Colloquially, the term "artificial intelligence" is often used to describe machines (or computers) that mimic cognitive functions that humans associate with the human mind, such as learning and problem-solving. (Source: Wikipedia)

Artificial Intelligence is rapidly shaping our future. Unlike the copied definition, here is an original thought: AI should not just be seen as a replacement for human work, but as a tool to amplify human creativity, improve decision-making, and handle repetitive tasks more efficiently. In the future, AI will likely integrate into daily life seamlessly, becoming invisible but highly impactful.

Page 2

Machine learning (ML) is a subset of artificial intelligence (AI) that provides systems the ability to automatically learn and improve from experience without being explicitly programmed. Machine learning focuses on the development of computer programs that can access data and use it to learn for themselves. The process of learning begins with observations or data, such as examples, direct experience, or instruction, in order to look for patterns in data and make better decisions in the future. (Source: Wikipedia)

Machine learning is not magic – it relies on data quality. An original insight here: without proper, unbiased, and diverse datasets, ML models tend to reinforce the same problems humans already have, such as biases or misinformation. Therefore, the responsibility of building ethical machine learning lies with developers and policymakers.

Page 3

Natural language processing (NLP) is a subfield of linguistics, computer science, and artificial intelligence concerned with the interactions between computers and human language, in particular how to program computers to process and analyze large amounts of natural language data. Challenges in natural language processing frequently involve speech recognition, natural language understanding, and natural language generation. (Source: Wikipedia)

Natural Language Processing is often confused with simply translating text. In reality, NLP is much broader – it enables chatbots, virtual assistants, summarization systems, and even sentiment analysis. A key original point is that NLP will likely evolve towards more context-aware and emotionally intelligent systems.
